# Newcommand

Sometimes you are building a huge project (like this lecture), and you may use certain type of syntax for many many times. Now it's time to define your own command with `\newcommand` in the beginning of the document (where the `\usepackage` commands appear).

## Command

```
\newcommand{\yourcommand}[arg_num]{code}
```

- `arg_num` - number of arguments in your command
- `code` - the code of your command, use `#1`, `#2`, ..., `#n` to represent the arguments

## Example

```
\newcommand{\samplecommand}[1]{\textbackslash  
#1}
```

It is defined to simply display the commands in red in

# Renewcommand

Another times you need to redefine the commands, then `\renewcommand` can be used. It's very similar to `\newcommand`, the only difference is that you must use `\newcommand` when the command doesn't exist, while using `\renewcommand` when the command has been defined (by you or L<sup>A</sup>T<sub>E</sub>X packages) before.

## Command

```
\renewcommand\definedcommand[arg_num]{code}
```

## Example

```
\renewcommand\thesection{\Roman{section}}  
\renewcommand\thesubsection{\Alph{subsection}}
```

By default, the number before the section titles of `\section` is 1, 2, 3, etc, this command will change them to a capital form of roman numbers, I, II, III, etc. And

# New/Renewenvironment

Environments can also be defined.

## Command

```
\newenvironment{name}[arg_num]{begdef}{enddef}  
\renewenvironment{name}[arg_num]{begdef}{enddef}
```

- `name` - the name of your environment
- `arg_num` - number of arguments in your environment
- `begdef` - the code to substitute the begin clause of your environment
- `enddef` - the code to substitute the end clause of your environment

## Example

```
\newenvironment{command}{\begin{block}{Command}}{\end{block}}
```

# Include and Input

When you are building a huge project, if you write all of the code in a single file, the compiling of the whole project will be very slow, and the length of the file will also confuse you. Then you can use `\include` and `\input` to avoid this.

## Command

`\include{file}` - Include the file on a new page, the files are compiled separately.

`\input{file}` - Directly replace the command with the whole file, doesn't start a new page, but the compiling won't speed up.

If you are including a .tex file, then the extension name can be omitted. Another command `\includeonly{list}` can be added to the beginning of the document, so that only the include files in `list` are compiled and others are ignored, this is very useful in debugging huge projects.

# Insert pdf

If you want to insert pdf files into your tex file, you can

## Command

```
1 \usepackage{pdfpages}  
2 \includepdf{file}
```

For typing formulas in L<sup>A</sup>T<sub>E</sub>X, besides equation environment, you can also use `mhchem` package. The documentation for `mhchem` can be referred at <http://ctan.mirrors.hoobly.com/macros/latex/contrib/mhchem/mhchem.pdf>

# Hyperlink

Hyperlinks are supported in L<sup>A</sup>T<sub>E</sub>X, use the `hyperref` package.

## Command

```
\usepackage{hyperref}  
\hypersetup{options}  
\url{url}  
\href{url}{text}
```

Some common `options` are listed below:

- `colorlinks` - boolean (default false)
- `urlcolor` - color for linked URLs (default magenta)
- `linkcolor` - color for normal internal links (default red)
